

Urban Lifestyle — Description

1. Overview

The Urban Lifestyle Dataset is a structured representation of cities distributed across major global regions.

Although synthetic, it is based on realistic trends reflected in urban development literature.

2. Purpose and Design Intent

This dataset was developed to:

- Provide a controlled environment for hands-on analytical investigation
- Encourage open questioning rather than fixed-output prediction
- Allow learners to experience real-world style variability without data quality issues

Its internal structure reflects realistic **correlation patterns, urban disparities, and regional variability**, making it suitable for clustering, similarity analysis, and data interpretation tasks.

3. Data Representation

Each record represents a **unique city**, characterized across multiple urban dimensions.

- **Mixed variable types**
 - Categorical: city identity and regional attributes
 - Numerical: socio-economic, environmental, and infrastructural indicators
- **No missing values**, allowing students to focus on modeling and interpretation

This balanced structure enables both statistical exploration and machine learning experimentation.

4. Analytical Value

The dataset supports the investigation of:

- **Economic development differences**
- **Infrastructure and service quality variations**
- **Environmental conditions and livability**
- **Social well-being indicators**

The absence of a target variable allows for **free-form exploration**, encouraging students to define their own research direction, questions, and insights.
